

# Container Slaves Plugin

## Plugin Information

No information for the plugin 'container-slaves-plugin' is available. It may have been removed from distribution.

Use Containers to setup build executors, without any constraint on images you can use.

The screenshot shows a configuration window titled "Run the build inside Docker containers". It features a "Main build container" field with the value "ubuntu:latest". Below this, there are two sections for "Side containers". The first section has a "Name" field with "database" and an "Images" field with "mysql", accompanied by a red "Suppressor" button. The second section has a "Name" field with "webserver" and an "Images" field with "jetty:9", also with a red "Suppressor" button. At the bottom left, there is a grey "Add a side container" button.

This plugin is currently under development, as a proposal for [Docker Global Hack Day](#).
