

Debian Pbuilder Plugin

Plugin Information

View Debian Pbuilder [on the plugin site](#) for more information.

This plugin lets you build Debian packages in a pbuilder environment, keeping a clean filesystem for builds.

Build Debian packages in Jenkins!

This plugin is based largely off of [jenkins-debian-glue](#), however with support for builder packages in a proper Jenkins way.

System Setup

Before you can successfully run the plugin, there are certain requirements that must be met on the node(s) that you wish to run on.

1. Install needed dependencies:

```
apt-get install qemu-user-static devscripts cowbuilder dpkg-dev
```

2. If building Debian packages on Ubuntu, make sure that the package `debian-archive-keyring` is installed
3. Like `jenkins-debian-glue`, make sure that `sudo` is configured properly. As taken from the `jenkins-debian-glue` webpage, add the following to either `/etc/sudoers`, or create a new file(e.g. `/etc/sudoers.d/jenkins`):

```
jenkins ALL=NOPASSWD: /usr/sbin/cowbuilder, /usr/sbin/chroot
Defaults env_keep+="DEB_* DIST ARCH"
```

(this assumes that Jenkins is running under the Jenkins user)

Using the Plugin

Configuration Options

There are several global configuration options. These options may be found by going to "Manage Jenkins" "Configure System".

- Email address - this is the email that is set in the changelog entry for the build. It need not be an actual email address
- Version format - Determines how the package will be versioned if not a tag build
- Debian directory - determines where the debian/ folder is, by default the project should be checked out to a directory called 'source'

Project Setup(Traditional)

This plugin may be configured as both a traditional Jenkins build, or as a Pipeline project.

1. Create a new project. If you want to build for multiple architectures, select "Multi-configuration project"
2. Checkout source code. When you checkout the source code for the project, it **should** be in a subdirectory called 'source'(this value can be changed on either a per-build configuration or globally). This can be done as either an SVN repository, or a git repository. To checkout to the proper directory using git, go to "Additional Behaviors" and select "Check out to a sub-directory", and put "source" as the value. To checkout to the proper directory using SVN, under "Local module directory" put "source" as the value.

The screenshot shows the Jenkins configuration for a Git repository. The 'Repositories' section has a 'Repository URL' field with the value 'https://github.com/rm5248/CSerial.git' and a 'Credentials' dropdown set to '- none -'. Below this are 'Advanced...' and 'Add Repository' buttons. The 'Branches to build' section has a 'Branch Specifier (blank for 'any')' field with the value '*/*master' and an 'Add Branch' button. The 'Repository browser' section has a dropdown menu set to '(Auto)'. The 'Additional Behaviours' section has a 'Check out to a sub-directory' option selected, with a 'Local subdirectory for repo' field containing the value 'source' and an 'Add' button.

The screenshot shows the Jenkins configuration for a Subversion repository. The 'Modules' section has a 'Repository URL' field with the value 'svn://svn.code.sf.net/p/dbus-cxx/code/trunk/dbus-cxx', a 'Credentials' dropdown set to '- none -', and an 'Add module...' button. Below this are 'Local module directory' (value: 'source'), 'Repository depth' (value: 'infinity'), and 'Ignore externals' (checked) fields. The 'Additional Credentials' section has an 'Add additional credentials...' button. The 'Check-out Strategy' section has a dropdown menu set to 'Use 'svn update' as much as possible'. A note below states: 'Use 'svn update' whenever possible, making the build faster. But this causes the artifacts from the previous build to remain when a new build starts.'

3. Under 'Build Environment', select 'Delete workspace before build starts'
4. If you have a matrix configuration project, add a new variable called "architecture". Put in the proper architectures to build for in this section; this must map to a valid architecture that exists in the distribution repos.

The screenshot shows the 'Configuration Matrix' and 'Build Environment' sections of the Jenkins configuration. The 'Configuration Matrix' section has a 'User-defined Axis' with a 'Name' field containing 'architecture' and a 'Values' field containing 'amd64 armhf'. Below this are 'Add axis', 'Combination Filter', 'Run each configuration sequentially' (checked), and 'Execute touchstone builds first' options. The 'Build Environment' section has a 'Delete workspace before build starts' option checked and an 'Advanced...' button. At the bottom, there is a 'Provide Configuration files' option.

- Under the 'Build' section, add 'Debian Pbuilder'. Most of these settings may be left at their default values, however it is highly recommended to fill in the "Distribution" and "Mirror Site" variables in order to ensure that you get a consistent build. Otherwise, pbuilder will use the defaults for whatever distribution you are currently running.

The screenshot shows the Jenkins configuration page for a 'Debian Pbuilder' build step. The 'Build' section is active, and the 'Debian Pbuilder' step is configured with the following settings:

- Number of cores: 1
- Distribution: jessie
- Mirror Site: http://cdn.debian.net/debian
- Build as tag:
- Additional Build Results: (empty text box)
- Architecture: (empty text box)

There is an 'Add build step' button at the bottom left of the configuration area.

- If you have custom pbuilder hook files that you want to install, install the [Config File Provider](#) to add in config files. Set the 'target' option to be 'hookdir/<file-name>'.

Project Setup(Pipeline)

If using pipeline, you may setup a job similar to the following:

Pipeline Setup - single arch

```
node(){
  ws{
    stage( "clean" ){
      cleanWs()
    }
    stage( "checkout" ){
      checkout([$class: 'GitSCM', branches:
        [[name: '*/jenkinsfile-updates']],
        doGenerateSubmoduleConfigurations: false,
        extensions: [[$class: 'RelativeTargetDirectory', relativeTargetDir: 'source']],
        submoduleCfg: [],
        userRemoteConfigs: [[credentialsId: '78de5c66-5dfb-4c95-8ad9-ec34e8dee4ec', url:
'git@github.com:rm5248/CSerial.git']]])
    }

    stage("build"){
      //Actually build the package.
      //Note that you can go to the 'Pipeline Syntax' page on your Jenkins instance to generate this
      automatically
      debianPbuilder additionalBuildResults: '', architecture: '', distribution: 'jessie', keyring:
'', mirrorSite: 'http://ftp.us.debian.org'
    }
  }
}
```

The following example shows how to build for multiple architectures:

Pipeline Setup - Multiple arch

```
def axisArchitecture = ["amd64", "armhf"]
def axisNode = ["master"]
def tasks = [:]

for( int i = 0; i < axisArchitecture.size(); i++ ){
    def arch = axisArchitecture[i];
    tasks["${axisNode[0]}/${axisArchitecture[i]}"] = {
        node(axisNode[0]){
            ws{
                stage( "clean" ){
                    cleanWs()
                }
                stage( "checkout" ){
                    checkout([$class: 'GitSCM', branches:
                        [[name: '*/jenkinsfile-updates']],
                        doGenerateSubmoduleConfigurations: false,
                        extensions: [[class: 'RelativeTargetDirectory', relativeTargetDir: 'source']],
                        submoduleCfg: [],
                        userRemoteConfigs: [[credentialsId: '78de5c66-5dfb-4c95-8ad9-ec34e8dee4ec', url:
                            'git@github.com:rm5248/CSerial.git']]])
                }
                stage("build-${arch}") {
                    debianPbuilder architecture:"${arch}"
                }
            }
        }
    }
}

stage('build'){
    parallel tasks
}
```

Package Versioning

By default the plugin will increment the current version number by reading 'debian/changelog'. The algorithm follows the standard Debian practice of packages having a ~ being a pre-release version, and packages with a + denoting a version greater than what is default. Note that this only happens if the the distribution set in 'debian/changelog' is UNRELEASED, or a tag is being built. Tags are automatically scanned; if using SVN or git, the environment variables SVN_URL_1 and GIT_BRANCH are scanned for the substring "tags/"; if the substring is found, the package will be built as a tag. Otherwise, you can also select the "Build as tag" to force the package to not increment the version number, or alternatively set the environment variable DEB_PBUILDER_BUILDING_TAG if you are building a tag.

Artifacts

All generated files are automatically added to the build artifacts for easy retrieval. This includes the deb files, as well as the dsc and tar files used to build the package in the pbuilder environment.

Output

All output can be found in the build output of the project when it is built. If for some reason the build fails, this is a good first place to look. If there is a configuration problem, a (hopefully) useful error message will be printed out when the build fails.

Building packages with 'quilt' format

When building a package with format "3.0 (quilt)", you must provide the orig.tar.gz file for the builder to work properly. This can be done one of two ways: either you can provide the orig.tar.gz through a pre-build step of some kind, or under the 'advanced' section there is a field for you to fill in the name of the package to checkout using the 'pristine-tar' command.

Issue Tracking

Please file any bugs that you may find on the Jenkins JIRA, using the debian-pbuilder-plugin component. [Click here](#) for all open issues.

Releases

Version 1.6(2019-04-21)

- Removed file lock when building packages; pbuilder should take care of this automatically and it probably doesn't work with multiple slaves anyway
- Catch correct exception if trying to create multiple chroots at the same time
- Added an option to change the pbuilder dependency resolver. Changing the dependency resolver fixes problems with apt segfaulting on an armhf chroot.
- Made the global configuration actually save and load correctly.
- Print out a more useful error message when the debian/source/format file doesn't exist or is bad.

Version 1.5(2019-01-27)

- Added ability to use pristine-tar to get orig.tar.gz file(JENKINS-52645)
- Added ability to set components when creating pbuilder base. This is mostly useful for building Ubuntu packages.

Version 1.4(2018-05-12)

- Added a setting for the keyring.
 - Auto-detection for building Debian packages on Ubuntu should still work, but this is useful for overriding it
 - Thanks to jaylawrence with [PR #1](#) for prompting this change

Version 1.3(2018-01-13)

- Plugin does not depend on pipeline
- Fixed JENKINS-48921

Version 1.2(2017-12-23)

- First official release on Jenkins.io
- No changes to code since version 1.1, only documentation/POM updates

Version 1.1

- Support for Pipeline jobs.
- Added configuration options for versioning

Version 1.0

- Initial Release of software. Can build projects of multiple types.
