Introduction

The Pretested Integration Plugin offers a branchy approach to pretested integration (also known as pre-tested commits), which upholds the invariant; that for a specific branch, known as the integration branch, all commits have been verified. This plugin is developed by [Praqma](#) and sponsored and maintained by the [Continuous Delivery Alliance](#) members (earlier named Josra)

The plugin relies on the SCM plugin to establish the workspace and then takes over to do the integration in the local workspace of the job. Finally the job makes the decision whether to like and push the result or hate and discard it.

Features

- If you deliver (git push) more than one commit on the **ready** branch it will be delivered to the integration branch using the strategy.

- Two strategies are supported: **squashed** (using git --squash merges) and **accumulated** (using git --no-ff merges).
- If you deliver one commit that can be fast-forwarded, it will be.
- Credentials support for the SCM configuration.
- Adding the Pretested Integration Plugin publisher as a post-build step is optional, leaving room for more customized jobs.
- The plugin support Job DSL, scripted and declarative pipeline syntax if you script your jobs.
- Pretested Integration Plugin can integrate repositories with git submodules if they are processed as part of the git scm additional behavior.

Major version 3 incompatible with earlier version

Starting with version 3.0.0 we have changed the plugin to work as a Git Plugin extension, so you will find under Additional behaviors in your Git SCM configuration.

Earlier it was a build wrapper which was configured in the "Prepare an environment for this build"

The change was necessary in order to support the new Pipeline job types and requires you to migrate your job configuration.

Migration guide from 2.x to 3.x

Job DSL

If you're using Job DSL to generate your jobs this is an easy fix. Just update your Job DSL script with the new syntax, which is show in the JobDSL example section below.

Manually created jobs

If you're creating your jobs manually, you'll need to manually reconfigure your jobs.

When updating the plugin your current configuration will not show so you need to know how your jobs was configured and make the analogue configuration as Git Plugin extension.

Example below in the pictures.

The names of the fields have not changed and the strategies remain unchanged as well.

The image displays two side-by-side screenshots of Jenkins configuration pages. The left screenshot is titled "Build wrapper" and shows the "Source Code Management" section with "Git" selected. It includes fields for "Repository URL" (https://github.com/Praqma/pretested-integration-plugin), "Credentials" (Pretested User/*****), "Branches to build" (*/ready**), and "Repository browser" (Auto). Below this, there are sections for "Additional Behaviours" (Clean before checkout), "Build Triggers" (Build after other projects are built, Build periodically, Poll SCM), "Build Environment" (Use pretested integration, Integration branch: master, Repository name: origin), and "Pre-tested integration strategy" (Accumulated commit, Squashed commit). The right screenshot is titled "Git 'Additional behaviour'" and shows the "Source Code Management" tab selected. It includes fields for "Repository URL" (https://github.), "Credentials" (Pretested Use), "Branches to build" (Branch Specifier (blank for 'any')), "Repository browser" (Auto), and "Additional Behaviours" (Clean before checkout). It also features a "Use pretested integration" section with "Integration branch" (master) and "Repository name" (origin), and a "Pretested integration" section with "Accumulated commit" and "Squashed commit" options.

Additional behaviours "Use pretested integration" -> Configure Integration branch and repository

Who should upgrade and who should not

- Users who rely on **Multiple SCM plugin should not upgrade to 3.x** since we've removed support for this plugin in 3.0.0. If you use this plugin, consider moving to the Pipeline job type instead and leave the deprecated MultiSCM behind.
- If you use **purely FreeStyle jobs in your environment, upgrading to 3.0.0 is recommended**. It won't provide any benefits and **won't be strictly necessary**, but we recommend to follow along and if you have many manual configured job, take the opportunity to script them using Job DSL or Jenkins Pipeline syntax.
- **If you use Matrix job, you can benefit from version 3.x** as the post build step is now optional and thus gives you flexibility to use pretested integration in a Matrix job setup.

Plugin limitations

There is one requirement: You should only try to integrate changes from one repository pr. job.

So see this as a limitation, but it actually a design decision as we will never be able to guarantee an atomic integration of two DVCS repositories as one process.

- **So only configure the Pretested Integration Plugin on one Git repository pr. job**

Beside this the Pretested Integration plugin works with most known job types :

- FreeStyle and Matrix jobs are supported. See the section below for configuring Matrix jobs.
- Pipeline jobs are also supported, with a small caveat for Multibranch Pipeline: The pipeline is executed before the merge of the Jenkinsfile, so changes you push for the Jenkinsfile will only have effect the next time the pipeline executes.
- Maven job type are unsupported and we will print a warning, but should function just like the FreeStyle Job type in many cases.

There can be more repositories in your job - only one under integration.

When you use Git SCM with more than 1 repository configured it is absolutely required that you ensure that the remote name is unique pr. repository as we only allow integration of 1 git repo per job. Call them by the saying repository name or simply just origin1, origin2 ...

For Pipeline you also need to make sure you only perform 1 integration in the course of the flow, you can have multiple checkouts, but only one of your repositories can have pretested integration happening, otherwise we cannot reliably determine which branch to delete upon the success of the job.

Changes in Jenkinsfile (for users of pipeline with Jenkinsfile)

The default behaviour of the pretested integration plugin is to run `jenkinsfile` that is located on the branch that is being integrated, so if branch `ready/457-uses-gradle-instead-of-maven` if being processed by the plugin, it is the file located on that branch that will be executed, not the one on the integration branch.

Conflicts

There can be cases where users have edited the jenkins file, and that can result in a merge conflict. The pretested integration plugin does not handle merge conflict in a Jenkinsfile, so to update the Jenkins file, another strategy must be applied.

1. Change the Jenkins file and merge it to the integration branch (`master`) locally in a separate commit
2. Push it to remote master
3. Delivering the other changes on a ready branch, which also has the updates to the jenkinsfile

If `master` (in the case above) is also being build by a job, that can result in a failing build if the new Jenkinsfile is using resources not yet available. This will however be fixed the moment the `ready`-branch have been integrated.

Comments and discussions on this page is not noticed.

Plugin configuration

Tips for matrix job configuration

When you use the Matrix Job type, the merge is performed for each child job in your matrix and even though the Pretested Integration Plugin post-build step is added we make sure it is only executed once in the parent job. This ensures that we only attempt to remove the branch once during a Matrix build after all child jobs have completed and have completed successfully.

We assume that your integration process using Pretested Integration Plugin is serialized so only one of this kind of job per project is building at the time. Else you're not sure the child jobs are integrating and verifying the same changes.

Manual building

In general you are not able to use 'Build now' with a Pretested Integration Plugin job configuration. The Pretested Integration Plugin is first in action when a "workspace" is handed over from the Git Plugin it will when manually building serve the last build revision again. If that succeeded last time, the revision is deleted after the integration and retrying the integration fails.

Some successful and failing cases using manual builds are:

- If last build failed, thus the integration failed, for a non-persistent error (disk problem, licensing problem ...) rebuilding the job can succeed if no other build have been executed since last time.
- If you have done a job configuration change, and need to trigger the job to test the configuration you typically need to make a commit that triggers the job. Push a commit to a ready branch, or wait for one.
- There is a work around, that often enables you to build manually: Make the job parametrized with `BRANCH_TO_BUILD` and use that variable in the 'branch specifier'. Make `BRANCH_TO_BUILD` have the default ready-branch specifier, so if not given the job works as if there were no parameters. If you now build the job manually, you can type in a branch to build.

Failed and 'Nothing to do' statuses when merging

The 'Nothing to do' build status is added to your build description in the following scenarios

- Pushing a development branch that has no changes (result of merge is empty)
- Using the plugin in a setup with more than 1 remote configured where the build is triggered by repository that does not have pretested integration plugin configured.

Failed builds can happen if there is a merge conflict which cannot be solved by a merge. In this scenario it is up to the user to merge the integration branch into their own development branch to fix their issues and deliver it again.

How Pretested Integration uses credentials

The Pretested Integration plugin will re-use the credentials for configured for the SCM that performed the merge. That means that if you've properly configured credentials in your git plugin, that is, credentials with write access to your repository no further configuration is required.

The recommended setup and git workflow

Here is a simple git workflow where you can work on a features branch, and when ready push to a **ready**-branch. The Pretested Integration plugin, if configured as described will then pick up your changes, merge them and verify them. If verified they are integrated on the **integration** branch. The ready branch are automatically deleted if integration was successful.

Recommendation:

- Use one repository in your job configuration - **the integration repository**. Avoid using several repositories - model your dependencies in other (better) ways.
- Name your repository **origin**
- Use **master** as **integration** branch (destination).
- Use **origin/ready**** as specifier for **ready** branches - only branches matching this expression will trigger the build

The simple Git workflow

Get your repository up to date:

```
git fetch --prune
git checkout master
git pull origin master
```

Create a feature- or development- or... branch

```
git checkout -b feat_1337-improved-login-screen
```

...work, stage and commit changes.

Then push changes to a **ready** branch, which is basically just a branch following a naming conventions for branches matching **ready/***.

```
git push origin feat_1337-improved-login-screen:ready/feat_1337-improved-login-screen
```

The change will be picked up by the plugin if configured as shown in the picture below.

- You can then delete your local branch and continue with a new feature or development branch.
- You are free to push to any branch name not matching the ready branch naming convention without triggering an integration build.

This is how the default configuration should look like:

The screenshot shows the Jenkins configuration page for Source Code Management, specifically for Git. The 'Source Code Management' tab is active. Under 'Repositories', the 'Repository URL' is set to 'https://github.com/praqma-test/pretested-integration-plugin-test-repo' and 'Credentials' is set to 'MadsNielsen/***** (my user)'. The 'Branches to build' section has a 'Branch Specifier (blank for 'any')' set to '*/ready/**'. The 'Repository browser' is set to '(Auto)'. Under 'Additional Behaviours', 'Clean before checkout', 'Prune stale remote-tracking branches', and 'Use pretested integration' are all checked. The 'Integration branch' is set to 'master' and the 'Repository name' is 'origin'. The 'Pretested integration strategy' section has 'Squashed commit' selected. There is an 'Add' button at the bottom of the 'Additional Behaviours' section.

And a publisher to delete on success:

The screenshot shows the Jenkins configuration page for Post-build Actions. The 'Post-build Actions' section is active. There is one action listed: 'Pretested Integration publisher to push to integration branch'. There is an 'Add post-build action' button at the bottom.

Integration flow

Below is a simplified diagram of what Pretested Integration actually does once you've pushed your branch to integrate. At the start, HEAD is at the integration branch, ready to merge in your branch. In the end the merge result is verified and, if successful, pushed.

Help and error messages

We tried to gather some common errors and problems seen, together with some suggested solutions but not much have been contributed. See [Help and error messages](#)

Scripted job examples

The following are examples on how to script jobs using this plugin. Refer to either the pipeline script generator in Jenkins or Job DSL API viewer for all the details.

Job DSL

Example integrating the plugin repository itself using our recommended default configuration

```

job("pretested-integration-plugin_our-integration-job") {
  scm {
    git {
      remote {
        name("origin")
        url("https://your.repo.com.git")
      }
      branch("*/ready/**")
      extensions {
        pretestedIntegration("SQUASHED", "master", "origin")
      }
    }
  }
  publishers {
    pretestedIntegrationPublisher()
  }
}
  
```

Scripted pipeline

Example integrating the plugin repository itself using our recommended default configuration

```

node {
  checkout([$class: 'GitSCM', branches: [[name: '*/ready/**']], doGenerateSubmoduleConfigurations: false,
extensions: [[class: 'CleanBeforeCheckout'], pretestedIntegration(gitIntegrationStrategy: squash(),
integrationBranch: 'master', repoName: 'origin')], submoduleCfg: [], userRemoteConfigs: [[credentialsId:
'pipCredentials', url: 'https://your.repo.com.git']]])
  pretestedIntegrationPublisher()
}

```

Declarative pipeline

Example integrating the plugin repository itself using our recommended default configuration

```

pipeline {
  agent any
  stages {
    stage("checkout") {
      steps {
        checkout([$class: 'GitSCM', branches: [[name: '*/ready/**']], doGenerateSubmoduleConfigurations:
false, extensions: [[class: 'CleanBeforeCheckout'], pretestedIntegration(gitIntegrationStrategy: squash(),
integrationBranch: 'master', repoName: 'origin')], submoduleCfg: [], userRemoteConfigs: [[credentialsId:
'pipCredentials', url: 'https://your.repo.com.git']]])
      }
    }
    stage("publish") {
      steps {
        pretestedIntegrationPublisher()
      }
    }
  }
}

```

Multibranch Pipeline Project

When configuring the plugin with multibranch projects the configuration is a little different. When you create your Multibranch Project you do not put the Pretested Integration extension in the SCM configuration as part of the branch source. Instead you need to configure the pipeline to ignore default checkout and perform the checkout in a step, where you do add the pretestedIntegration extension. Like so:

Multibranch Declarative Example

```

pipeline {
  agent any
  options { skipDefaultCheckout() }
  stages {
    stage("checkout") {
      steps {
        checkout([$class: 'GitSCM', branches: [[name: '*/ready/**']],
doGenerateSubmoduleConfigurations: false, extensions: [[class: 'CleanBeforeCheckout'], pretestedIntegration
(gitIntegrationStrategy: squash(), integrationBranch: 'master', repoName: 'origin')], submoduleCfg: [],
userRemoteConfigs: [[credentialsId: 'pipCredentials', url: 'https://your.repo.com.git']]])
      }
    }
    stage("publish") {
      steps {
        pretestedIntegrationPublisher()
      }
    }
  }
}

```

Usage scenarios

As a developer using CLI

See this link: [Link to usage with the CLI](#)

As a developer using Eclipse

Follow the guide [Using Eclipse](#)

Issues

See [Github issues](#) for current backlog and known issues.

Changes

Version 3.1.0

- Fixed an issue that caused build to continue, even though integration failed in the SCM step.
- Added option to shorten the merge commit message for the Accumulated commit strategy.
- Minor correction to output in console.

Version 3.0.1

- Identical to 3.0.0 we just changed version number to not include git SHA as it breaks compatibility with Jenkins Docker install-plugins.sh script and is not fully semver compliant.

Version 3.0.0 incl. betas - Not backwards compatible!

The overall changes in 3.0.0 all have to do with making the plugin pipeline compatible. No changes to the behaviour of the plugin are in this new release.

- Scripted pipeline support
- Declarative pipeline support
- Optional post build step, merge result is now optional
- Can be used with Matrix jobs since publisher is now optional.
- Deprecated use of MultiSCM Plugin

Version 2.4.1

- Made a clearer error message when the plugin fails to push empty commits. ([#15](#))

Version 2.4.0

- Added Credentials plugin support by replacing remaining CLI calls with GitClient implementations. ([issue #29104](#))
- No longer refuses to integrate branches whose names contain 'master'. (Still blocks integration of 'master'.) ([issue #31138](#))
- No longer marks builds with SUCCESS if the Pretested Integration step fails. ([issue #30465](#))
- Fixed post-install plugin description. ([issue #31388](#))
- Plugin version is now printed to console. ([issue #31139](#))

Version 2.3.4

- Single commits are fast-forward merged when possible. ([issue #30891](#))

Version 2.3.3

- Added a license. ([issue #31058](#))

Version 2.3.2

- Updated to compile with newer versions of Jenkins ([issue #27343](#))
- Added JobDSL support ([issue #30192](#))
- Added variable expansion for input fields ([issue #30885](#))

Version 2.3.1

- Squash integration strategy no longer replaces the message of single commits. ([issue #30603](#))

Version 2.3.0

- More logging and information in general for better debugging and understanding why builds fail. Part of feature implementation and re-factoring for [JENKINS-27690](#), [JENKINS-28590](#)
- Output to build console is extended and streamlines between the two different integration strategies ([JENKINS-28590](#))

- [JENKINS-28590](#): Author of the integration commit is the author of the last commit on the development branch (instead of always the build user).
- [JENKINS-28596](#): It is possible for the accumulated to use a custom integration branch, a bug was fixed in this area.
- Test were written to check commit message with quotes will not fail integration ([JENKINS-27662](#)). There are still issue though, reported in **unfixed issue [JENKINS-28640](#)**
- Changed test strategy toward static git repositories, that are added as test resources for the functional tests
- [JENKINS-27697](#): Improvements around releasing files for test repositories, so functional tests for the plugin will also run on Windows
- [JENKINS-29369](#): Changed accumulated commit message date strings to be English locale. (**Not fixed is that timezone still local - see [JENKINS-29377](#)** and discussion here: <https://trello.com/c/aY5d8Sxd/130-jenkins-29377-date-formatting-should-be-utc-in-accumulated-msg>)
- [JENKINS-28640](#): Quotationmarks in commit message is replaced with single plings, as using quotationmarks lead to merge failure as they were not escaped properly.

Version 2.2.3

- [JENKINS-27516](#) Plugin hangs - reproduced with failed earlier build. A regression problem, related to never Jenkins cores and that the plugin used semaphores. Problem was seen, by the plugin prints the version number in the job console and then the job hangs.

Version 2.2.1

- [JENKINS-26568](#) New accumulated commit message. Almost identical to what you get from squash commit, thus it have much more traceability by including the commit messages from all included commits.

Version 2.2.0

- [JENKINS-25445](#) Support for checkout to subdirectories.
- [JENKINS-24754](#), [JENKINS-25544](#), [JENKINS-25546](#) Support for using the [Multiple SCMs Plugin](#).
- [JENKINS-25886](#) Requiring explicitly named remotes if using Multiple SCMs Plugin
- [JENKINS-25960](#) Fixed problem with resolving correct git scm and remotes, if using Multiple SCMs Plugin
- [JENKINS-25959](#) Post-build step, publish the changes to remote, is blocked if trying to delete 'master'-branch (using it as ready-branch)
- [JENKINS-25618](#) Changed squashed merge strategy commit message, to include all the squashed commits individual messages.
- [JENKINS-25873](#) Changed to using custom version number for this plugin, by adding git SHAs

Version 2.1.2

- Implemented logging tracing

Version 2.1.1

- Bugfix for running on slaves ([JENKINS-24844](#))

Version 2.1.0

- Protected master branch (Plugin tries to delete origin/master [JENKINS-24286](#))
- Re-using last commit message in accumulated strategy (Improve commit message [JENKINS-24285](#))
- Removed the "origin" from the description ([JENKINS-24284](#))
- When squashing commits, now using author from tip of branch ([JENKINS-24443](#))
- Additional tests added as well

Version 2.0

- Git integration is now supported

Version 1.1

- Dependency of Mercurial plugin set to 1.39 due to previous failure to trigger on merge commits
- Removed UI elements that should not have been there

Version 1.0

- Release of the first stable version
